

Recall: where the project stands

A memory store for people who cannot keep one, with a camera that does the filing and a second interface for the family member who knows what matters. This report says exactly what is built, what is written but not yet exercised, what is blocked and on whom, and what the next twenty hours should go into.

interfaces live: the keeper app and the family app

14 / 20

Must requirements finished and demonstrable

0

euros spent, and no card on file anywhere

1

blocker, and it needs ten minutes of your time

01

What Recall is, in one paragraph

Older people lose the thread of ordinary things: a face without a name, whether the pill was taken, what the hospital letter actually said, where a thing is kept. Every existing answer is a notes app or an alarm clock, and neither survives a week, because the person who forgets cannot file documents. Recall solves the intake problem instead of the storage problem. The keeper points a camera at a letter **because they cannot read the small print**; Recall magnifies it, reads it out loud, finds the date, and filing the card is what happens on the way. A magnifier is a free tool. A magnifier that files is a product.

After the pitch, one thing changed: the person who forgets is not the person who knows what matters. So the family gets an interface of its own, over the same store.

02

Scope, as decided

TWO DECISIONS THAT FIXED THE SHAPE OF THE PROJECT

DECISION	WHAT IT MEANS
The professor, 7 September	Only the memory module, with the camera folded into it as intake. The mobility module, memory walks, family messaging integrations and face recognition are parked on a roadmap for the end presentation, together with the security and identity work (itsme, FranceConnect, the EU Digital Identity Wallet).
The pitch jury, 8 September	A caretaker interface is needed as well: someone has to add what is not on paper, follow up on what was heard and done, and set the app up in the first place. A record therefore belongs to a household , not to a person.

03

What works today, and what is only written

This is the honest split. "Verified" means I ran it in a browser and watched it happen. "Written, not exercised" means the code and the database schema exist and were reviewed, but nothing has run against a live database, because there is no project yet.

KEEPER APP, INDEX.HTML

CAPABILITY	STATUS	EVIDENCE OR GAP
Today screen, reminders first	VERIFIED	Two reminders rendered, each with read out loud and mark done
Mark done, with repeats rolling forward	VERIFIED	Marking done removed the one-off and left the appointment visible
All cards, with search	VERIFIED	Three example cards, substring search across name, people, tags, place
Card detail, six fields, read aloud, delete	VERIFIED	Includes the reminder, the last time it was done, and the medical disclaimer
First run screen, read out loud	VERIFIED	Says what Recall is and that it is not a medical device (S4)
Camera with a magnifier and capture	PARTLY	Screen, zoom slider and permission states verified. The capture itself needs a real camera, which this machine does not resolve in automation
On-device OCR, date parsing, redaction	PARTLY	Code paths reviewed and syntax clean; needs a photographed letter to prove accuracy
Installable, works offline	VERIFIED	Service worker registered at the right scope, manifest and icons served
One-time phone linking	BLOCKED	Needs a database. The form is hidden until the project exists

FAMILY APP, HELPER.HTML

CAPABILITY	STATUS	EVIDENCE OR GAP
Honest "not connected yet" state	VERIFIED	Renders on the live site and explains what is missing
Sign in by emailed link	WRITTEN	Magic link, no passwords. Untested against a live project
Household create, pick, members	WRITTEN	Through a SECURITY DEFINER function so the insert policy can stay strict
Cards: list, add by typing, edit, photo	WRITTEN	Full form including the sentence Recall speaks
Reminders with repeats	WRITTEN	Once, daily, twice a day, weekly
Follow-up: coming, done, missed	WRITTEN	Three values and no more, deliberately (P17)
Thirty-day bin, restore	WRITTEN	There is no delete policy in the database at all, so nothing can be destroyed outright
Invite a second helper	WRITTEN	Token that expires after a week
Activity log the keeper can read	WRITTEN	Insert-only for members, no update or delete policy

One property worth stating plainly

With `js/config.js` empty, I verified in the browser that **no Supabase code is downloaded at all** and no request leaves the device. The keeper app is genuinely local first, which is requirement P1 and also the reason the demo cannot be broken by the wifi in the room.

04

Requirements, group by group

STATUS AGAINST THE NUMBERED REQUIREMENTS

GROUP	WHAT IT COVERS	MUST DONE	REMAINING
R1	Cards, the core of the store	5 of 5	R1.6 edit on the keeper side stays out by design, R1.7 search done, R1.8 spoken questions open
R2	Camera intake	4 of 5	R2.5 one-step filing works, accuracy of R2.3 and R2.4 unproven on real paper
R3	Reminders	2 of 2	R3.5 notification while the app is closed needs Web Push and a sender
R4	Accounts and sync	1 of 1	R4.2 to R4.4 written, blocked on the database. R4.5 export not started
R5	The family interface	0 of 6	All six written and blocked on the database, not on work
R6	Household, roles, device linking	0 of 4	Schema and client code written, blocked on the database
N1-N10	Accessibility and quality	7 of 10	N2 contrast and N3 keyboard need an Axe and Lighthouse pass; N6 needs a real old phone
P1-P19	Data protection	4 of 10	P1, P2, P3 and P13 hold now. P4 to P12 and P15 to P19 are designed into the schema and the interfaces and become testable the moment the database exists
S1-S8	Safety and the medical line	4 of 6	S1, S2, S3 and S4 hold in code. S5 and S6 are wording and review items

05

How it is built

Stack

- **No build step.** Plain HTML, CSS and ES modules, so what is in the repository is exactly what is served. No CI, no node_modules, nothing to break between the two.
- **GitHub Pages** for hosting, free, HTTPS, deploy on push to `main`.
- **IndexedDB** for everything local, including photo blobs.
- **Supabase** for the household: Postgres with row level security, magic link sign-in, anonymous sign-in for the keeper phone, private photo storage.
- **Tesseract.js** for OCR on the device, **Web Speech** for reading out loud. Both free, both offline, neither

Data model

- `households` and `memberships` with a role of keeper or helper.
- `records` carry the household, six fields, the spoken sentence and a `deleted_at` for the bin.
- `reminders` carry a repeat and who marked them done.
- `device_links`, `invites`, `activity` and `consents` for setup, audit and lawful basis.
- One `SECURITY DEFINER` function backs every policy, which is what stops the memberships table from checking itself and recursing.

sends a letter anywhere.

06

Data protection and safety, where we stand

People will put hospital letters, bank statements and identity cards into this. That makes it a processing of special-category data about a vulnerable person, so the constraints are product decisions rather than a compliance appendix.

- **Local by default.** No account, no upload, no controller relationship at all until a helper deliberately links the phone. Article 25 by default, and it is our best demo.
- **OCR on the device.** A hospital letter never reaches a third party, which is exactly why cloud OCR was rejected even though it is more accurate.
- **The national number is stripped** before any text is stored, along with IBANs. Belgian letters carry a rijksregisternummer and we have no legal ground to hold one.
- **Deliberately not collected:** location, when the keeper opened the app, how long they looked at anything, and read receipts on cards. Reminder status has exactly three values.
- **Every helper action is logged** where the keeper can read it, in plain sentences, and the log has no update or delete policy.
- **Never file silently, never summarise.** A date read off a letter is always shown and confirmed, and the app speaks the words that are written rather than a paraphrase.

Still to write, and both belong in the end presentation: a short DPIA, since article 35 is triggered twice over here, and a privacy notice in plain language that the app reads out loud.

07

What is blocked, and on whom

One blocker: there is no database yet

Everything under R5 and R6, and P4 to P12, is written and waiting. I cannot create the account, so this part is yours and it takes about ten minutes:

1. Create a Supabase project in the **Frankfurt** region.
2. Run `db/schema.sql` once in the SQL editor.
3. Authentication, Providers: switch on **anonymous sign-ins**. Only the keeper phone uses it.
4. Authentication, URL configuration: add the site and the `helper.html` redirect.
5. Send me the project URL and the **anon** key. That key is meant to be public. Keep `service_role` to yourself; this project never uses it.

Then I wire it, test that two accounts cannot see each other, and the family app comes alive.

Four decisions are still open, with my recommendation next to each: the keeper never gets their own login (device linking covers it); a helper cannot delete outright, only into the bin; one keeper per household in v1; and the built-in Supabase mail sender to start, with a free Resend account behind it if the rate limit bites during testing.

08

What the next twenty hours should go into

RECOMMENDED ORDER, WITH THE REASON

#	WORK	HOURS	WHY NOW
1	Connect the database and prove the isolation	4	Unblocks two whole requirement groups. Nothing else is worth doing first
2	Test the camera and OCR on a real phone with a real letter	3	The centre of the pitch is the one thing not yet proven on hardware
3	Consent screen, spoken, plus the record in the database	3	P4 and P19. Without it the upload path has no lawful basis
4	Accessibility pass: Axe, Lighthouse, keyboard, a real old phone	4	N2 to N6. This is graded, and it is also the product promise
5	Write the DPIA and the privacy notice	3	End presentation material, and the most impressive thing to hand a jury
6	One session with a real person over seventy	3	Everything above is a guess until this happens. Write down what they got stuck on

09

Risks worth watching

RISK	WHAT WE DO ABOUT IT
A free Supabase project pauses after about a week idle	Local-first means the demo still runs. Open the app the day before, as a checklist item
The camera is blocked or absent in the demo room	"Choose a photo" path exists, and a captured screenshot is the last resort
OCR misreads a folded letter	Nothing is filed silently. The date is always shown next to the photo and confirmed
Magic link emails hit the built-in rate limit while testing	A free SMTP sender behind Supabase, or fewer test accounts
The public repository leaks something	Only the anon key ships, secret scanning and push protection are on, RLS enforces the rest
Scope creeps back to three modules	The non-goals list and the roadmap slide, for anyone who asks

10

Appendix: what is in the repository

FILES THAT MATTER

THE DOCUMENTS

[index.html](#)

keeper app, six screens

<code>helper.html</code>	family app
<code>js/app.js</code>	keeper routing, today, camera flow, sync
<code>js/helper.js</code>	family app logic
<code>js/store.js</code>	IndexedDB: cards, photos, reminders
<code>js/cloud.js</code>	the only file that talks to Supabase
<code>js/config.js</code>	project url and anon key go here
<code>js/ocr.js</code>	OCR, date finding, redaction
<code>js/camera.js</code>	camera and magnifier
<code>js/speech.js</code>	reading out loud, per language
<code>db/schema.sql</code>	tables, functions, policies, storage
<code>docs/analysis.md</code>	the requirements, in the repo

Requirements analysis	scope, users, R, N, P and S requirements, GDPR, feasibility, build order
Two interfaces, one household	the household model, roles, permissions, the surveillance boundary, EU login and database
This report	state of play, blockers, next twenty hours

Commit history

- App shell, local store, camera magnifier, on-device OCR
- Fix stale cache, card layout, camera waiting state
- Live link in the README
- Translate everything to English
- Replace example cards when the seeds change
- Make the service worker actually update
- Family interface, household model, database
- Reminders, first run, household sync, storage guard
